### Chapter I

#### Introduction

C++ is a general-purpose programming language created by Bjarne Stroustrup as an extension of the C programming language, or "C with Classes" (source: Wikipedia).

The goal of these modules is to introduce you to **Object-Oriented Programming**. This will be the starting point of your C++ journey. Many languages are recommended for learning OOP, but we decided to choose C++ since it's derived from your old friend C. Because this is a complex language, and in order to keep things simple, your code will comply with the C++98 standard.

We are aware that modern C++ is quite different in many aspects. So, if you want to become a proficient C++ developer, it is up to you to go further after the 42 Common Core!

#### Chapter II

#### General rules

#### Compiling

- Compile your code with c++ and the flags -Wall -Wextra -Werror
- Your code should still compile if you add the flag -std=c++98

#### Formatting and naming conventions

- The exercise directories will be named this way: ex00, ex01, ..., exn
- Name your files, classes, functions, member functions and attributes as required in the guidelines.
- Write class names in **UpperCamelCase** format. Files containing class code will always be named according to the class name. For instance: ClassName.hpp/ClassName.h, ClassName.cpp, or ClassName.tpp. Then, if you have a header file containing the definition of a class "BrickWall" standing for a brick wall, its name will be BrickWall.hpp.
- Unless specified otherwise, every output messages must be ended by a new-line character and displayed to the standard output.
- Goodbye Norminette! No coding style is enforced in the C++ modules. You can follow your favorite one. But keep in mind that a code your peer-evaluators can't understand is a code they can't grade. Do your best to write a clean and readable code.

#### Allowed/Forbidden

You are not coding in C anymore. Time to C++! Therefore:

- You are allowed to use almost everything from the standard library. Thus, instead of sticking to what you already know, it would be smart to use as much as possible the C++-ish versions of the C functions you are used to.
- However, you can't use any other external library. It means C++11 (and derived forms) and Boost libraries are forbidden. The following functions are forbidden too: \*printf(), \*alloc() and free(). If you use them, your grade will be 0 and that's it.

- Note that unless explicitly stated otherwise, the using namespace <ns\_name> and friend keywords are forbidden. Otherwise, your grade will be -42.
- You are allowed to use the STL in the Module 08 and 09 only. That means: no Containers (vector/list/map/and so forth) and no Algorithms (anything that requires to include the <algorithm> header) until then. Otherwise, your grade will be -42.

#### A few design requirements

- Memory leakage occurs in C++ too. When you allocate memory (by using the new keyword), you must avoid memory leaks.
- From Module 02 to Module 09, your classes must be designed in the **Orthodox** Canonical Form, except when explicitly stated otherwise.
- Any function implementation put in a header file (except for function templates) means 0 to the exercise.
- You should be able to use each of your headers independently from others. Thus, they must include all the dependencies they need. However, you must avoid the problem of double inclusion by adding **include guards**. Otherwise, your grade will be 0.

#### Read me

- You can add some additional files if you need to (i.e., to split your code). As these assignments are not verified by a program, feel free to do so as long as you turn in the mandatory files.
- Sometimes, the guidelines of an exercise look short but the examples can show requirements that are not explicitly written in the instructions.
- Read each module completely before starting! Really, do it.
- By Odin, by Thor! Use your brain!!!

Regarding the Makefile for C++ projects, the same rules as in C apply (see the Norm chapter about the Makefile).

You will have to implement a lot of classes. This can seem tedious, unless you're able to script your favorite text editor.

You are given a certain amount of freedom to complete the exercises. However, follow the mandatory rules and don't be lazy. You would miss a lot of useful information! Do not hesitate to read about theoretical concepts.

## Chapter III

## New rules

From now on, all your classes must be designed in the **Orthodox Canonical Form**, unless explicitly stated otherwise. They will then implement the four required member functions below:

- Default constructor
- Copy constructor
- Copy assignment operator
- Destructor

Split your class code into two files. The header file (.hpp/.h) contains the class definition, whereas the source file (.cpp) contains the implementation.

## Chapter IV

## Exercise 00: My First Class in Orthodox Canonical Form

You think you know integers and floating-point numbers. How cute.

Please read this 3 pages article (1, 2, 3) to discover that you don't. Go on, read it.

Until today, every number you used in your code was basically either an integer or a floating-point number, or any of their variants (short, char, long, double, and so forth). After reading the article above, it's safe to assume that integers and floating-point numbers have opposite characteristics.

But today, things will change. You are going to discover a new and awesome number type: **fixed-point numbers**! Forever missing from the scalar types of most languages, fixed-point numbers offer a valuable balance between performance, accuracy, range and precision. That explains why fixed-point numbers are particularly applicable to computer graphics, sound processing or scientific programming, just to name a few.

As C++ lacks fixed-point numbers, you're going to add them. This article from Berkeley is a good start. If you have no idea what Berkeley University is, read this section of its Wikipedia page.

Create a class in Orthodox Canonical Form that represents a fixed-point number:

- Private members:
  - An **integer** to store the fixed-point number value.
  - A static constant integer to store the number of fractional bits. Its value will always be the integer literal 8.
- Public members:
  - A default constructor that initializes the fixed-point number value to 0.
  - A copy constructor.
  - A copy assignment operator overload.
  - A destructor.
  - A member function int getRawBits(void) const; that returns the raw value of the fixed-point value.
  - A member function void setRawBits( int const raw ); that sets the raw value of the fixed-point number.

#### Running this code:

```
#include <iostream>
int         main( void ) {

Fixed a;
Fixed b( a );
Fixed c;

c = b;

std::cout << a.getRawBits() << std::endl;
std::cout << b.getRawBits() << std::endl;
std::cout << c.getRawBits() << std::endl;</pre>
```

#### Should output something similar to:

```
$> ./a.out

Default constructor called

Copy constructor called

Copy assignment operator called // <-- This line may be missing depending on your implementation

getRawBits member function called

Default constructor called

Copy assignment operator called

getRawBits member function called

getRawBits member function called

0

getRawBits member function called

0

Destructor called

Destructor called

Destructor called

Destructor called

Destructor called

Destructor called
```

## Chapter V

# Exercise 01: Towards a more useful fixed-point number class

-	Exercise 01			
Towards a more useful fixed-point number class				
Turn-in directory : $ex01/$				
Files to turn in : Makefile, main.cpp, Fixed.{h, hpp}, Fixed.cpp				
Allowed functions: roundf (from <cmath>)</cmath>				

The previous exercise was a good start, but our class is pretty useless. It can only represent the value 0.0.

Add the following public constructors and public member functions to your class:

- A constructor that takes a **constant integer** as a parameter. It converts it to the corresponding fixed-point value. The fractional bits value should be initialized to 8, like in exercise 00.
- A constructor that takes a **constant floating-point number** as a parameter. It converts it to the corresponding fixed-point value. The fractional bits value should be initialized to 8, like in exercise 00.
- A member function float toFloat( void ) const; that converts the fixed-point value to a floating-point value.
- A member function int toInt( void ) const; that converts the fixed-point value to an integer value.

And add the following function to the **Fixed** class files:

• An overload of the insertion («) operator that inserts a floating-point representation of the fixed-point number into the output stream object passed as a parameter.

#### Running this code:

#### Should output something similar to:

```
$> ./a.out
Default constructor called
Int constructor called
Float constructor called
Copy constructor called
Copy assignment operator called
Float constructor called
Copy assignment operator called
Destructor called
a is 1234.43
b is 10
c is 42.4219
d is 10
a is 1234 as integer
b is 10 as integer
c is 42 as integer
d is 10 as integer
Destructor called
Destructor called
Destructor called
Destructor called
```

#### Chapter VI

## Exercise 02: Now we're talking

Exercise 02				
Now we're talki	ng			
Turn-in directory : $ex02/$				
Files to turn in : Makefile, main.cpp, Fixed.{h, hpp}, Fixed.cpp				
Allowed functions: roundf (from <cmath>)</cmath>				

Add public member functions to your class to overload the following operators:

- The 6 comparison operators: >, <, >=, <=, and !=.
- The 4 arithmetic operators: +, -, \*, and /.
- The 4 increment/decrement (pre-increment and post-increment, pre-decrement and post-decrement) operators, which will increase or decrease the fixed-point value by the smallest representable  $\epsilon$ , such that  $1 + \epsilon > 1$ .

Add these four public overloaded member functions to your class:

- A static member function min that takes two references to fixed-point numbers as parameters, and returns a reference to the smallest one.
- A static member function min that takes two references to **constant** fixed-point numbers as parameters, and returns a reference to the smallest one.
- A static member function max that takes two references to fixed-point numbers as parameters, and returns a reference to the greatest one.
- A static member function max that takes two references to **constant** fixed-point numbers as parameters, and returns a reference to the greatest one.

It's up to you to test every feature of your class. However, running the code below:

Should output something like (for greater readability, the constructor/destructor messages are removed in the example below):

```
$> ./a.out
0
0.00390625
0.00390625
0.00390625
0.0078125
10.1016
10.1016
$>
```

If you ever do a division by  $\mathbf{0}$ , it is acceptable that the program crashes

## Chapter VII

Exercise 03: BSP

Now that you have a functional **Fixed** class, it would be nice to use it.

Implement a function that indicates whether a point is inside a triangle or not. Very useful, isn't it?

BSP stands for Binary Space Partitioning. You are welcome. :)

You can pass this module without completing exercise 03.

Let's start by creating the **Point** class in Orthodox Canonical Form that represents a 2D point:

- Private members:
  - A Fixed const attribute x.
  - A Fixed const attribute y.
  - Anything else useful.
- Public members:
  - $\circ$  A default constructor that initializes x and y to 0.
  - $\circ$  A constructor that takes two constant floating-point numbers as parameters. It initializes x and y with those parameters.
  - A copy constructor.
  - A copy assignment operator overload.
  - A destructor.
  - Anything else useful.

To conclude, implement the following function in the appropriate file:

bool bsp( Point const a, Point const b, Point const c, Point const point);

- a, b, c: The vertices of our beloved triangle.
- point: The point to check.
- Returns: True if the point is inside the triangle. False otherwise. Thus, if the point is a vertex or on an edge, it will return False.

Implement and turn in your own tests to ensure that your class behaves as expected.

# Chapter VIII Submission and Peer-Evaluation

Turn in your assignment in your Git repository as usual. Only the work inside your repository will be evaluated during the defense. Don't hesitate to double-check the names of your folders and files to ensure they are correct.
